Interactive comment on “The interaction of ocean acidification and carbonate chemistry on coral reef calcification: evaluating the carbonate chemistry Coral Reef Ecosystem Feedback (CREF) hypothesis on the Bermuda coral reef” by N. R. Bates et al.

J. Silverman (Referee)
jacobs1@stanford.edu

Received and published: 22 September 2009

I strongly support publication of this paper after revision.

This paper is among the few papers to show the dependence of coral calcification on the aragonite degree of saturation from in situ measurements. More importantly the authors have demonstrated convincingly that the threshold for decalcification due to ocean acidification speculated on in previous reports has already been crossed in the C2100
Bermuda reef. It is expected that the time period during an annual cycle in which this reef decalcifies will lengthen significantly within the next ten years. Thus, the process of decalcification will be gradual and not abrupt at least in subtropical reefs assuming the seasonal cycle of $pCO_2$ superimposed on the anthropogenic increasing trend in the water flushing them remains consistent, i.e. similar amplitude. This point may be interesting to address in another study. As a result the atmospheric $pCO_2$ threshold for decalcification is set even lower than proposed in earlier studies at least for subtropical reefs. While I do support the publication of this paper in this journal I have a number of comments that I think will help improve the manuscript as detailed below.

Specific comments:

1) The title of the manuscript is too long and doesn’t make sense, especially the first part, i.e. it isn’t clear what interacts with what. Perhaps it should be “The response of coral calcification to ocean acidification: . . .”, or “Redefining the decalcification threshold of coral growth in response to Ocean acidification: . . .”.

2) There are a number of references appearing in the text, which don’t appear in the list of references. I have gone over just the first 28 lines of the introduction (p. 7629) and found a number of missing refs: Buddemeier 1996, Buddemeier and Smith 1999, Wilkinson 1998 and 1999. It is not clear which Edmunds is referred to in 2007 (there are 2 in the list). I didn’t bother going over the rest of the refs, there are probably some that are missing further on and some that weren’t referred to in the text but appear in the list.

3) Table 1 – You could include the data from Silverman et al. (Biogeochemistry (2007) 84:67–82) for both diurnal and seasonal ranges in this table as well as other studies, such as Gattusso et al. (1996) with a little extra work.

4) p. 7629 l. 5: it is not clear what reference refers to what effect, partly because of the missing refs in the bibliography. What ref refers to the deleterious effect that sea level rise has already had on modern coral reefs?
5) p. 7629 l. 4: is sedimentation increasing due to global change? Should this be increased sedimentation rates rather than increasing?

6) p. 7629 l. 14: why is partial of CO\textsubscript{2} referred to in the plural?

7) p. 7629 l. 13-14 – “For example, over the last few decades, dissolved inorganic carbon (DIC) and partial pressures of CO\textsubscript{2} (pCO\textsubscript{2}) have increased while pH has decreased”. The way it is written one could understand that ocean pH decreases independently of atmospheric CO\textsubscript{2} increase, which is of course wrong.

8) p. 7629 l. 22 – “…will increase as W values…” should be Ω.

9) p. 7629 l. 21-24 – “In addition, it is also likely that the dissolution of carbonate sediments and structures will increase as W values decline in the future (Wollast et al., 1980; Andersson et al., 2003; Morse et al., 2006; Yates and Halley, 2006; Andersson et al., 2006, 2007, 2009)”. To the best of my knowledge there are no observations that support this statement. Yes, observations have shown dissolution at high pCO\textsubscript{2} but none have shown any coherent dependence of CaCO\textsubscript{3} dissolution on pCO\textsubscript{2} (except for the modeling papers).

10) p. 7629 l. 25-28 – “Experimental studies have shown that the ability and the rate at which coral reefs calcify decrease as a result of ocean acidification, decreasing seawater [CO\textsubscript{2}-3] and Ω (e.g. Gattuso et al., 1998, 1999; Marubini and Atkinson, 1999; Marubini and Thake, 1999; Langdon et al., 2000; Langdon, 2001; Langdon and Atkinson, 2005)”. The ref to Gattuso et al., 1998 is inaccurate because in this study artificial seawater was used and the Ω\textsubscript{arag} was manipulated through changes in concentrations of Ca\textsuperscript{+2} and not CO\textsubscript{2}-3. Additionally, Ω in the manuscript should be Ω\textsubscript{arag}, i.e. the saturation state of the aragonite mineral which is precipitated by corals.

11) p. 7630 l. 1 – “Observations from coral colonies and coral reef community mesocosms exposed and equilibrated with high levels of atmospheric CO\textsubscript{2} (500–700 ppm) and lowered [CO\textsubscript{2}-3] concentration (with lower values of Ω with respect to aragonite)
have generally shown reduction in the rates of coral calcification”. Should probably be mesocosms exposed to seawater equilibrated with high ... You should also decide what units to use for partial pressure of $pCO_2$ (ppm or ) and use them throughout the entire manuscript.

12) p. 7630 l. 20-22 - Field studies have subsequently indicated that rates of calcification are 3–5 times greater in the light than in the dark (Gattuso et al., 1999; Schneider and Erez, 2006), ...”. The Schneider and Erez study is not a field study.

13) p. 7630 l. 22 – p. 7631 l. 6 – this whole section describes briefly the physiological process of bio-mineralization in corals based on the current literature which has no bearing whatsoever on the methodology, results, relations and conclusions which are presented in the following. Therefore I think that this section should be withdrawn entirely from the manuscript.

14) p. 7631 l. 14 – 17 – “With ocean acidification, it has been proposed that the combination of reduced rates of calcification and increased rates of $CaCO_3$ dissolution could result in coral reefs transitioning from net accumulation to a net loss in $CaCO_3$ material...”. Again the increase in dissolution rates statement is unfounded see item 9 above.

15) p. 7632 l. 1 – 3 – “As stated earlier, there is very limited field data on the relationships between calcification and carbonate chemistry (with the exception of Silverman et al., 2007), particularly over seasonal to annual timescales”. You should include Ohde and van Woesik in the first ref and with respect to seasonal to annual timescales you should cite Silverman et al. (2007).

16) p. 7632 l. 12 – you wrote contain and should be constrain.

17) p. 7632 l. 19 – you wrote “threshoulds” should be thresholds.

18) p. 7633 – p. 7634 – section 2.2 is extraneous and tedious, just state what apparent thermodynamic equilibrium constants were used in your calculations. Also, no need
to mention what equations were used to resolve the carbonate system, it should be obvious. If you like you can refer the uninitiated reader to Zeebe and Gladrow (2001) for a complete description of the carbonate system equations.

19) p. 7635 l. 13 – you wrote “thermister” should be thermistor.

20) p. 7635 – it is unclear from this section or Fig 1 where CARIOCA was deployed (on the reef flat, in the lagoon). It would be best to indicate this important information on the Site map (Fig 1).

21) p. 7636 l. 21 – 22 – it is unclear from the text and the following discussion of the results what the normalization of DIC and $A_T$ was used for if at all in the analysis and interpretation of the results of this study.

22) p. 7636 l. 24 – p. 7637 l. 8 – while, the method used to get at the PAR value at the surface is quite convoluted and impressive it is unclear how you obtained atmospheric transmittance ($T_r$) considering the wide range that you cite (what value or values were used?). Wouldn’t it be easier to get pyranometer measurements from the Bermuda Station, which is run by Ellsworth Dutton and can be contacted at (Ellsworth.G.Dutton@noaa.gov)? It seems from the GEWEX site (http://www.gewex.org/datasets.html) that the data is available for free.

23) p. 7638 l. 19 – The authors cite a report (MEP, 2006) and refer the reader to a website where he/she can download the nutrient data presumably (http://www.biosmep.info/). Unfortunately, the following links only allow you to download an executive summary of the report, which I’m not certain are relevant to the period of measurement 2002-2003 as opposed to 2006 of the report. Under these conditions it would be helpful to show at least a figure of the available annual cycles demonstrating the consistent cyclical nature of this parameter.

24) p. 7638 l. 20-23 – The authors state that salinity varies annually within a range of 36 to 36.8 PSU, yet it is not clear if precipitation during summer is the major cause
for reduced salinity in the lagoon (local) or is this a more general characteristic of the region.

25) p. 7641 l. 6-8 – “If the in situ skeletal growth rates observed at Hog Reef are scaled up, we estimate that the calcification rate per unit area of the reef ranged from 1.9 to 13.1 g CaCO$_3$ m$^{-2}$ d$^{-1}$, assuming a range of coral cover from 30–70.

26) p. 7641 l. 15-18 – “The annual rate of calcification per unit area of the reef is estimated at Hog Reef to range between 0.5 and 3.5 kg CaCO$_3$ m$^{-2}$ year$^{-1}$, slightly lower than the average calcification rate of 4±0.7 kg CaCO$_3$ m$^{-2}$ year$^{-1}$ reported for other coral reefs (Kinsey, 1985)”. Taking the average of the range and not the max rate the change in calcification relative to Kinsey’s rate is 35.

27) p. 7643 – 7645 section 4.3 – see item 13 above.

28) p. 7652 l. 12-14 – at least show a figure of the data from 2009.

29) In the conclusions as well as throughout the discussion the authors disregard the effect of temperature on coral calcification despite the fact that coral growth has been shown to have an optimum dependence on temperature in a number of previous studies. Since the temperature range over an annual cycle is quite large at the Bermuda site the “disagreement” between the apparent coral growth independence of temperature in this study and the previously reported relation in experimental studies requires additional consideration rather than just cursory acknowledgement. Silverman et al. 2007 and 2009 consider the dependence of coral growth on temperature and $\Omega_{arag}$, perhaps it would be useful to test the relation that they propose with your data.

30) Table 2 – what do the errors represent (min-max, STD, SE)?

31) The time scale in Fig. 2 is unclear, its hard to tell when the year begins and when it ends.
