Interactive comment on “Seasonal Variability of Tropical Wetland CH₄ emissions: the role of the methanogen-available carbon pool” by A. A. Bloom et al.

Anonymous Referee #2

Received and published: 7 March 2012

This manuscript by Bloom et al. well describes temporal patterns of CH₄ emission from physical conditions (temperature and moisture) and substrate availability. This is a well-written paper, and their ideas are presented clearly.

I strongly agree with the reviewer 1 that the authors should explicitly consider alternative hypothesis.

I also suggest them to evaluate their simple model. In previous studies, there are more detailed, more mechanistic models. For example, Walter & Heimann (2000, Global Biogeochemical Cycles) explicitly modeled CH₄ transport including diffusion, ebullition, and vascular transport. They also explicitly simulated CH₄ oxidation in aerobic soil layers. I think the thickness of aerobic soil layers could strongly control CH₄ dynamics in a way that is not treated by this manuscript by Bloom et al. So, please explain why your simple model is appropriate for this study.
