The point-by-point response to the reviews

Response to reviews of manuscript “Trade-offs between water loss and carbon gain in a subtropical primary forest on Karst soils in China” bg-2018-44

Dear Editor,

We deeply appreciate you for giving us an opportunity to revise our manuscript. Here are the point-to-point responses (responses in upright Roman) to the comments (original queries in Italic). Meanwhile, we have rephrased our manuscript title as “The strategies of water-carbon regulation of plants in a subtropical primary forest on Karst soils in China”.

Response to Associate Editor comments

Here are the point-to-point responses to the comments (original queries in Italic).

1) Please rephrase the starting sentence by highlighting the importance of trade off between water loss and carbon gain and its implication. And the key characteristics of Karst can be briefly introduced.

Response: Thanks a lot for your comment and suggestion. In response, we have rephrased the starting sentence of Abstract as “Coexisting plant species in a Karst ecosystem may use diversity strategies of trade off between carbon gain and water loss to adopt to the low soil nutrient and water availability conditions.” (see Page 2 lines 31-33).

Meanwhile, we have rephrased the first paragraph in Section “Introduction” as “Diversity strategies of trade off between carbon gain and water loss are critical for the survival of coexisting plant species. In order to adapt to the harsh environment, coexisting plant species develop distinct patterns of strategies of carbon-water
regulation (light-saturated net photosynthesis ($A$) and intrinsic water use efficiency ($i\text{WUE}$)) (Sullivan et al., 2017). $i\text{WUE}$ is the ratio of $A$ to stomatal conductance to $H_2O$ ($g_{sw}$) (Moreno-Gutierrez et al., 2012). Plants with high $i\text{WUE}$ are better able to adapt to the nutrient- and water-limited environment (Flexas et al., 2016). Due to the greater hydraulic erosion and complex underground drainage network (Nie et al., 2014; Chen et al., 2015), Karst soils cannot retain enough nutrients and water for plant growth even though precipitation is high (1000-2000 mm) (Liu et al., 2011; Fu et al., 2012; Chen et al., 2015). Understanding of the impact of $CO_2$ diffusion and maximum carboxylase activity of Rubisco ($V_{cmax}$) on $A$ and $i\text{WUE}$ in Karst plants can provide insight into physiological strategies of water-carbon regulation of plants used in adaptation to Karst environments at the leaf scale. Until now, variability in $A$ and $i\text{WUE}$ has been reported only in 13 co-occurring trees and 12 vines (Chen et al., 2015), and 12 co-occurring tree species (Fu et al., 2012) in two tropical Karst forests in southwestern China.”. (see Page 3 lines 57-73).

2) In addition the manuscript needs to be carefully checked for some typos.

Response: Thanks a lot for your comment. We have carefully checked and corrected the typos.

Response to reviewer#1

Specific comments

(1) I feel the explanation and justification of the chosen methodology for measuring and calculating mesophyll conductance should be in the Materials and Methods section, not in the discussion. It takes away from your actual results.

Response: Thank you for your suggestion. This section have been moved to Section “Materials and Methods” according to your suggestion. (see Page 7 lines 182-198).
(2) Although an “in review” article is cited in the materials and methods, I think this is not an acceptable description of methodology (line 140). This should be written out in detail as I cannot access the information from there. I would like to have more details about leaf sampling and measurements. What were the temperature and humidity chosen for the measurements? How were the leaves collected? Did you collect leaves or twigs which you then cut under water or did you collect separate leaves which you measured in the field? Did you measure fluorescence? Could you calculate your results with the Harley method as well? It is common nowadays to confirm your results with a second method as all methods have some constraints.

Response: Thank you for your suggestions. In response, we have revised the Section “Materials and Methods” in two aspects. Firstly, we have added more details about leaf sampling and measurements in Section “Materials and Methods”. Such as, we have added the method of how to collect and prepare the leaves before CO₂ response curves measurements. (see Page 6 lines 154-162). Meanwhile, we have described the method and conditions of CO₂ response curves measurements in more detail. (see page 6 lines 164-168).

Secondly, we clarified that gm was estimated by the ‘curve-fitting’ method in this study (see page 7 line191). As the fluorescence was not measured in this study, the Harley method cannot be used to calculate gm. Details about why we choose the ‘curve-fitting’ method to calculate gm, and the data valid confirmation have been added. (see page 7 lines 191-198).

(3) I would also like to see more detail and justification in the statistical analysis section of the materials and methods

Response: Thank you for your comment. In response, we have revised the Section “2.5 Statistical analysis” in two aspects. Firstly, we have moved the Section “2.4 Quantitative analysis of limitations on A” to Section “2.5 Statistical analysis”. (see page 9 line 251 to page 10 line 265). Secondly, we have added more details about the
statistical analysis in Section “2.5 Statistical analysis” (see Section “(2) Data analysis”, page 10 line3 267-283). Such as, we have added the data analysis method. (see page 10 lines 268-269). We have added the bivariate linear regressions method. (see page 10 lines 269-271). We have added what method used to compare the difference of linear regressions. (see page 10 lines 273-279).

(4) In the results, you bring out that gs was better correlated with A, but lm was more limiting. This would be important to discuss in detail in the discussion. This is an extremely important result.

Response: Thank you for your comment and suggestion. In response, we have reanalyzed our data, and revised Section “4.1 Co-variation in gs, gm and Vcmax in regulating A”. Firstly, we analyzed the relationships between CO2 diffusion conductance (gs and gm) and Vcmax, compared the relative limitations of gs, gm and Vcmax to A, and analyzed the relationships between the limitation factors and the corresponding relative limitations. Consequently, we have revised the corresponding results in Section “4.1 Co-variation in gs, gm and Vcmax in regulating A”. (see page 12 line 343 to page 13 line 354). In brief, A was significantly correlated with gs, gm, and Vcmax (Fig.3a-c). gs was positively related to gm (Fig.S1c), while no relationship was found between the CO2 diffusion conductance (gs and gm) and Vcmax (Fig. S2). ls, lm and lb of 63 species varied in a large range (Fig. S3), indicating plants have a diverse strategies to co-ordinate the CO2 diffusion (gs and gm) and Vcmax to maintain relative high A. The order of factors limitations to A was lm> lb >ls (P<0.05) (Fig.S3). Furthermore, ls, lm, and lb were negatively associated with gs, gm, and Vcmax, respectively (Fig. 4). And the relationship was stronger for gm- lm (r2=0.65) than Vcmax- lb (r2=0.27) and gs- ls (r2=0.19).

Secondly, we have discussed two possible reasons of the corresponding results in Section “4.1 Co-variation in gs, gm and Vcmax in regulating A”. (see page 13 lines 356 -363). In brief, gs was better correlated with A, while the results showed that A was more limited by gm. That could be explained by two possible reasons. Firstly,
compare to the linear relationship between $A$ and $g_s$, a nonlinear trend has been found between $A$ and $g_m$ when $g_m>0.4$ (Fig. 3a, b). Secondly, leaf structure plays an important role in regulating $g_m$ and $V_{cmax}$, consequently, in determining $A$ (Veromann-Jurgenson et al., 2017). Negative relationships between $A$/LMA and LT ($r^2=0.16$, $p=0.002$), and $A$/LMA and LT ($r^2=0.3$, $p<0.001$) have been observed (Fig. S4c,d), while $A$ was not correlated to LT and LD (Fig. S4a,b).

(5) The conclusions are a bit flat, I would like to see the paragraph rephrased so it is a bit more exciting.

Response: Thank you for your comment. The Section “Conclusions” has been rephrased as: “This study provides information of limitations of $A$ and iWUE by $g_s$, $g_m$, and $V_{cmax}$ in 63 species across 6 life forms in the field. The results showed that plants growing in Karst CZs used a diverse strategies of carbon-water regulation, but no difference was found among life forms. The co-variation of CO$_2$ supply ($g_s$ and $g_m$) and demand ($V_{cmax}$) regulated $A$, indicating that species maintain a relatively high $A$ through co-varying their leaf anatomical structure and $V_{cmax}$. iWUE was relatively low, but ranged widely, indicating that plants used the ‘profligate/opportunistic’ water use strategy to maintain the survival, growth, and structure of the community. iWUE was regulated by $g_s$, $V_{cmax}$, $g_m/g_s$ and $V_{cmax}/g_s$, indicating that species with high $g_m/g_s$ or $V_{cmax}/g_s$ will have to be much more competitive to response to the ongoing rapid warming and drought in the Karst CZs.”. (see page 17 line 489 to page 18 line 499).

(6) Figure 5 needs an explanation about the whiskers: are they SEs or SDs? If they are SEs, I do not find it likely that gm was indeed the most important limiter in vines and ferns, but only grasses.

Response: Thank you for your suggestion and comment. We clarified that whiskers in Figure 5 was standard deviation. The Figure 5 legend rephrased as: “Figure 5. Limitation to light-saturated net photosynthesis ($A$) in six life forms by stomatal conductance to CO$_2$ ($l_s$), mesophyll conductance to CO$_2$ ($l_m$), and the maximum
carboxylase activity of Rubisco ($l_b$). Error bars denote standard deviation.”. (see page 31 lines 788-789).

Technical comments

(7) Line 31: grammatical error, should be “plants’”

Response: This sentence has been deleted.

(8) Line 38: delete first “and”

Response: Deleted. Thank you. (see page 2 line 38).

(9) Line 38: add “their” between “measured” and “CO2”

Response: Change has been made. Thank you. (see page 2 line 38).

(10) Line 38: … calculated “the” corresponding...

Response: Change has been made. Thank you. (see page 2 line 39).

(11) Line 73: replace “indeed” with “however”

Response: This change has been made. (see page 3 line 79).

(12) Line 84: within “a” leaf.

Response: Change has been made. Thank you. (see page 4 line 90).

(13) Line 110: delete “The”. Sentences should not be started with an article before an abbreviation. This is bad style.

Response: Deleted. Thank you. (see page 5 line 116).
(14) Lines 125 and 126: this sentence should be in the present if the soil conditions are unlikely to radically change in a short period of time.

Response: Change has been made. (see page 5 lines 132-133).

(15) Line 130: same comment as the previous, should be in the present if this does not change rapidly.

Response: Change has been made. (see page 5 line 137).

(16) Line 140: You cannot use “were” if the article you are citing is still in review. This is chronologically incoherent.

Response: Thank you for your suggestion and comment. The cited article has been accepted by “Scientific Reports”. And this sentence has been rephrased as “More details were described in Wang et al. (2018)” (see page 6 lines 171-172).

(17) Line 148: the citation is doubles, delete one

Response: Deleted. Thank you. (See page 7 line 177).

(18) Line 153: delete “The”

Response: Deleted. Thank you. (See page 7 line 191).

(19) Line 161: no need to redefine abbreviations in each section – once is enough

Response: Change has been made. (See page 7 line 202).

(20) Line 166: this sentence needs to be rephrased. Stomata are not a barrier inside the leaf, like this sentence seems to claim.
Response: Thank you for your suggestion and comment. Rephrased as: “Mesophyll is the barrier for CO₂ inside the leaf.” (See page 8 line 208).

(21) *Line 214: last equation was 8, this should be 9*

Response: This changed have been made. Thank you. (See page 9 line 257).

(22) *Line 253: both implies 2 variables: delete “both of”*

Response: Deleted. (See page 11 line 310).

(23) *Line 256: delete “The”*

Response: Deleted. (See page 11 line 313).

(24) *Line 257: move “respectively” to the end of the sentence*

Response: Change has been made. Thank you. (See page 11 line 314).

Response: Deleted. (See page 11 line 315).

(26) *Line 271: delete “The”*

Response: Deleted. (See page 11 line 315).

(27) *Line 272: Change to “Grasses”*

Response: Change has been made. Thank you. (See page 12 line 342).

(28) *Line 273: Change to Accordingly, grasses”*

Response: Change has been made. (See page 12 line 323).
(29) Line 276: delete “The”

Response: Deleted. (See page 12 line 328).

(30) Line 284: delete “The”

Response: Deleted. (See page 12 line 336).

(31) Line 295: Recent work has compared Harley, Ethier and the anatomical models finding good correlations, so I would not write largely unknown, rather "to some extent"

Response: Rephrased as: “Thus, the accuracy of each method is to some extent unknown (Warren, 2006).” (See page 7 lines 188-189).

(32) Line 353: this sentence should be rephrased, leads to the impression that you also did ultrastructural sampling

Response: Thank you for your suggestion and comment. Rephrased as: “The importance of $g_m$ in constraining $A$ was variable, and depended on leaf structural traits, only LMA, LT, and LD were analyzed in this study.” (See page 13 lines 365-366).

(33) Lines 368-374: chloroplasts do not have cell walls, the sentences need to be rephrased

Response: Thank you for your suggestion and comment. This mistake has been corrected: “cell wall thickness of mesophyll”. (See page 13 lines 372-373).

(34) Line 402: “highly efficient”

Response: This change has been made. (See page 15 lines 424-425).
(35) Line 411: delete the first “in this study”

Response: Deleted. (See page 15 line 433).

(36) Line 415: “lose” not “loss”

Response: Corrected. Thank you. (See page 16 line 456).

(37) Lines 416-417 “The results …”: unnecessary sentence, delete

Response: Deleted.

(38) Line 422: full stop missing from the end

Response: Added. Thank you. (See page 16 line 438).

(39) Line 424: delete “The”

Response: This change has been made. (See page 16 line 461).

(40) Lines 424-425 stating with “In theory”: should be in the present

Response: This change has been made. (See page 16 line 461).

(41) Line 433: This sentence should be in the present

This change has been made. (See page 16 line 466).

(42) Line 448: ...inefficiency in “the” trade-off

Response: This change has been made. (See page 17 line 485).

(43) Line 452: “low nutrient”

Response: This change has been made. (See page 16 lines 451).
(44) Line 461: iWUE is not in italic in any other place

Response: This change has been made. (See page 17 line 489).

(45)Line 462: ...forms in “the” field

Response: This change has been made. (See page 17 line 490).

(46) Line 463: ... used “a” diverse

Response: Change has been made, thank you. (See page 17 line 491).

(47) Line 464: ... maintain “a” relatively

Response: This change has been made. (See page 17 line 493).

(48) Line 465: ... used “the”

Response: Thank you for your suggestion and comment. Chang has been made. (see page 17 line 495).

(49)Line 483: “References”

Response: Change has been made. (See page 18 line 513).

Response to reviewer#2

General comments:

(1) The author use “Trade-offs between water loss and carbon gain” in the title, however, the whole-text actually talk about the limitation of different components on A and iWUE.
Response: Thanks a lot for your comment. We response to this comment from two aspects. On one hand, we have rephrased our manuscript title as “The strategies of water-carbon regulation of plants in a subtropical primary forest on Karst soils in China”.

On the other hand, we have revised the Section “Discussion”. Firstly, we have re-organized and revised Section “4.1 The role of $g_m$ in CO$_2$ diffusion and $V_{c_{\text{max}}}$”, and merged it with “4.2 Co-variation in $g_s$, $g_m$ and $V_{c_{\text{max}}}$ in regulating $A$”. Such as, the explanation and justification of the chosen methodology for measuring and calculating $g_m$ have been moved to Section “Materials and Methods” according to Reviewer#1’s comment. (see Page 7 lines 182-198). Paragraphs “Uncertainties introduced by ignoring $g_m$.” have been deleted. We have revised, corrected and re-organized the paragraph “Large variability in $g_m$”, and merged it with “4.2 Co-variation in $g_s$, $g_m$ and $V_{c_{\text{max}}}$ in regulating $A$”. (see page 13 lines 365-377).

Secondly, we have revised the title of Section “4.2 Co-variation in $g_s$, $g_m$ and $V_{c_{\text{max}}}$ in regulating $A$” as “4.1 Co-variation in $g_s$, $g_m$ and $V_{c_{\text{max}}}$ in regulating $A$”. And we have re-analyzed our data, and rephrased the Section “4.1 Co-variation in $g_s$, $g_m$ and $V_{c_{\text{max}}}$ in regulating $A$” to discuss about the limitation of different components on $A$ and iWUE. (see page 13 line 339 to page 15 line 412). In brief, Karst plants have a diverse strategies to co-ordinate the CO$_2$ diffusion ($g_s$ and $g_m$) and $V_{c_{\text{max}}}$ to maintain relative high $A$. $A$ was regulated by the co-variation of $g_s$ and $g_m$. The strong investment in supportive structures was the main reason for the limitation of $g_m$ on $A$. The wide variation range of $l_b$ (0.11-0.68) highlighted the importance role of $V_{c_{\text{max}}}$ in regulating $A$. The trade-off between CO$_2$ supply ($g_s$ and $g_m$) and demand (carboxylation capacity of Rubisco) can help maintain relative high $A$.

Thirdly, we have revised the title of Section “4.3 Co-variation in $g_s$, $g_m$ and $V_{c_{\text{max}}}$ in regulating iWUE” as “4.2 Co-variation in $g_s$, $g_m$ and $V_{c_{\text{max}}}$ in regulating iWUE ”. To emphasize the diverse carbon-water regulation strategies of plants in Karst CZs, and
highlighted the role of trade-off between carbon gain and water loss, we have revised the Section “4.2 Co-variation in $g_s$, $g_m$ and $V_{c_{\text{max}}}$ in regulating iWUE”. (see page 15 line 430 to page 17 line 486). In brief, coexisting plant species growing in the Karst ecosystem had a diversity water use strategies. However, Karst plants tended to lose more water to gain more carbon, i.e. Karst plants used ‘profligate/opportunistic’ water use strategy to adopt to the low nutrient availability and water stress conditions. iWUE was correlated to $g_s$, $V_{c_{\text{max}}}$, $g_{\text{m}}/g_s$ and $V_{c_{\text{max}}}/g_s$.

(2) In the method section: The species covered wide range of functional groups, including 6 life forms. What the criteria of the species selection? Because the leaf habit (evergreen or deciduous), the shade or light-demanding behaviors also will affect the strategy of plant carbon-water regulation. For example, does fern grow in the canopy or understory, how you can put them together when analyze the data? More important, the main objective of this paper was to determine and distinguish the limitations of CO2 diffusion and Vcmax on A and iWUE in different life forms Karst forest, however, you combine all species together for most analysis, actually we donot know what’s the difference between different life forms in Figs 1-4, 6,7. I Believe most land plant will behave in similar way to adapt to the environmental factor no matter where they grow, the interesting things is to what extent by different plants. For example, Based on Fig 5, we could not see any difference among the groups. So, I suggest the author should separate into 6 groups to see the differences of regression lines among groups for all the figures, and compare the difference among the life forms using proper statistical method.

Response: Thank you for your comments and suggestions. We response to revised the manuscript from three aspects according to your comments and suggestions. Firstly, we have added our criteria of the species selection in Section “2.2 Leaf gas-exchange measurements”. (see page 6 lines 145-152). In brief, the species sampled were selected according to their abundance in the study site. They are the main component of this forest. To distinguish the strategies of water-carbon regulation of plants among
different life forms, those species were grouped into 6 life forms, including Tree, Tree/Shrub, Shrub, Grass, Vine, and Fern. “Tree/Shrub” is a kind of low wood plant between Tree and Shrub. Fern grow in understory. Vine climb up to the shrub canopy to get light. Meanwhile, we have added how to collect and sample leaves. (see page 6 lines 154-162). For example, Branches exposed to the sun were excised from the upper part of the crown or aboveground portion, and immediately re-cut under water to maintain xylem water continuity.

Secondly, we have re-analyzed our data either as a whole group (six life forms combined) or by individual life forms, and the difference between different life forms was tested using the standardized major axis (SMA) regression fits. The results showed that no significantly difference between life forms. Thus six life forms were grouped together to analyze the strategy of water-carbon regulation of plants in the whole text. The statistical method and results have been added in Section “2.5 Statistical analysis”. (see page 10 lines 268-279).

Thirdly, all of data of six life forms were separately presented in Figure 1-4, 6,7 and Figure S1,S2, S4-S6 (See Supplement). Only the regression line for 63 species were presented in figures.

(3) lines 139-140, because the A-Ci curve is the key data of this paper, author should describe in detail how this measurement was done rather than just cite other submitted papers. For example, you should introduce the height of your targeted individuals? how you can measure the sun-exposed leaf for canopy trees and climbing plants: : : ?did you measure in situ or cut down, if the latter, for A-Ci curve you normally need ca. 30 min, how you can avoid the effects of cutting on stomatal conductance because some species are very sensitive, do you have some information on the gs sensitivity for those species: : : .

Response: Thank you for your suggestions. In response, we have added more details
about leaf sampling and measurements in Section “Materials and Methods”. Such as, we have added the method of how to sample and prepare the leaves before CO₂ response curves measurements. (see page 6 lines 154-162). In brief, branches exposed to the sun were excised from the upper part of the crown or above the ground, and immediately re-cut under water to maintain xylem water continuity. Back into the laboratory, branches were kept at 25°C for 30 min. Fully-expanded and mature leaves were induced for 30 minutes at a saturating light density. CO₂ response curves measurements were performed when A and gₛ was stable. However, the height of targeted individuals did not measured.

Meanwhile, we have described the method and conditions of CO₂ response curves measurements in more detail. (see page 6 lines 164-172). In brief, the CO₂ response curves were measured with 11 CO₂ concentration gradients in chamber following the procedural guidelines described by Long and Bernacchi (2003). The photosynthetic photon flux density was 1500 μmol m⁻² s⁻¹. The leaf temperature was 25°C, controlled by the block temperature. The humidity in the leaf chamber was maintained at ambient condition.

Specific comments:

(4) Line 267-269: There is no statistic tests of the differences of the results in figure 5, so it is not proper to give the statements in line 309-310. Figure 5 can’t give any information that is about LMA. Please use data to demonstrate the relationship between LMA and other parameters instead of qualitative description.

Response: Thank you for your comments and suggestions. We response to the comments and suggestions from two aspects. Firstly, we have analyzed the data of figure 5 using statistical method, and revised the corresponding Sections. Such as, we have added statistical method used to test the difference of the results in figure 5 in Section “2.5 Statistical analysis” “The difference of relative limitation of gₛ, gₘ and Vₑₘₐₓ to A for life forms or as a whole group were performed using one-way ANOVA
and Duncan multiple comparison. The probability of significance was defined at p<0.05.” (see page 10 lines 281-283).

Meanwhile, we have re-drew figure 5 and revised corresponding results in the Section “3.2 Contribution of gs, gm and Vcmax to A”. (see page 11 line 314 to page 12 line 325).

In brief, the contributions by gs, gm, and Vcmax to limiting A were different for each species (Fig. S3). Overall, lm was significantly larger than lb, and ls (P<0.05). There was no significantly difference between ls, lm and lb for Trees and Tree/shrubs. lm of Shrubs and Grasses was significantly higher than that of ls and lb (P<0.05). lm of Vines and Ferns was significantly higher than that of ls (P<0.05) (Fig. 5). Meanwhile, we have revised the corresponding results and discussions in Section “4.1 Co-variation in gs, gm and Vcmax in regulating A”. (see page 12 line 340 to page 13 line 354).

Secondly, we have tested the difference of LMA across life forms using one-way ANOVA and Duncan multiple comparison. The results showed that no difference of LMA was found among life forms. Consequently, lines 309-310 have been removed. We have tested the role of leaf structure (leaf thickness (LT) and leaf density (LD)) in A, gm and Vcmax, and rephrased the Section “4.1 Co-variation in gs, gm and Vcmax in regulating A”. (see page 13 line 365 to page 14 line 389). In brief, No significant difference of LMA, LT, and LD was found among life forms (P<0.05). There was a significant relationship between gm/LMA with LMA (P<0.01), however, no relationship was found between gm with LMA. gm/LMA was significantly negative related to LD (p<0.01) (Fig. S5c), and weak negative related to LT (p=0.06) (Fig. S5d), demonstrating that the negative role of cell wall thickness on gm (Terashima et al., 2006; Niinemets et al., 2009).

(5) Line 372: Species with low LMA may have thick cell walls in mesophyll and chloroplast.
Response: Thank you for your suggestion. We have tested the difference of LMA across life forms using one-way ANOVA and Duncan multiple comparison. The results showed that no difference of LMA was found among life forms. Meanwhile, we have tested the role of leaf structure (leaf thickness (LT) and leaf density (LD)) in A, \(g_m\) and \(V_{c_{\text{max}}}\). The results showed that leaf structure plays important role in regulating \(g_m\) and \(V_{c_{\text{max}}}\), consequently, in determining \(A\). Thus, we revised the corresponding section in “4.1 Co-variation in \(g_s\), \(g_m\) and \(V_{c\text{max}}\) in regulating \(A\)”. (see page 12 line 340 to page 13 line 354). In brief, No significant difference of LMA, LT, and LD was found among life forms (P<0.05). There was a significant relationship between \(g_m/\text{LMA}\) with LMA (P<0.01), however, no relationship was found between \(g_m\) with LMA. \(g_m/\text{LMA}\) was significantly negative related to LD (p<0.01) (Fig. S5c), and weak negative related to LT (p=0.06) (Fig. S5d), demonstrating that the negative role of cell wall thickness on \(g_m\) (Terashima et al., 2006; Niinemets et al., 2009).

(6) Line 381-382: In your results, \(g_s\) and \(g_m\) are positively correlated, why did you conclude \(g_m\) is a compensate for reductions in \(g_s\)? Did you observe an increasing of \(g_m\) when \(g_s\) decreased.

Response: Thank you for your comment. We corrected this mistake, and we rephrased this paragraph as: “\(g_s\) is responsible for CO\(_2\) exchange between atmosphere and leaf, and regulate the CO\(_2\) fixation (A) and water loss (Lawson and Blatt, 2014). The variability of \(g_s\) was controlled by stomatal anatomy, i.e. stomata density and size, and mesophyll demands for CO\(_2\) (Lawson and Blatt, 2014). However, the stomatal anatomy was not analyzed in this study. We only focused on how the relationship between \(g_s\) and \(g_m\) regulate A. Positive relationship between \(g_s\) and \(g_m\) has been observed (Flexas et al., 2013). For example, the restricted CO\(_2\) diffusion from the ambient air to chloroplast is the main reason for a decreased A under water stress conditions due to both the stomatal and mesophyll limitations (Olsovska et al., 2016). \(g_s\) was significantly positive related to \(g_m\) for 63 species (P<0.001, Fig. S1) in this study, and no difference of the slopes of regression lines between \(g_s\) and \(g_m\) was found.
among life forms, demonstrating that A was regulated by the co-variation of $g_s$ and $g_m$. However, the variability of $g_m$ and $l_m$ was larger than $g_s$ and $l_s$, respectively (Fig.1 and Fig.S3).” (see page 14 lines 391-403).

(7) Line 384-389: I don’t think you have enough evidences to state “there was a trend of increasing $l_m$ with increasing leaf N:P”, unless you add this part of research in your draft.

Response: Thank you for your comment. There was no significant statistical relationship between $l_m$ and leaf N:P ($P=0.66$). We corrected this mistake, and rephrased this paragraph: “The wide variation range of $l_b$ (0.11-0.68) highlighted the importance role of $V_{cmax}$ in regulating A. $V_{cmax}$ was used to represent the CO$_2$ demand in photosynthetic process in this study. The relative contribution of $V_{cmax}$ to A not only depends on $C_a-C_c$, but also on leaf nutrient levels. Positive relationship was found between $C_a-C_c$ and $V_{cmax}$ (Fig. 1d). And the $V_{cmax}$/LMA was co-regulated by leaf N, P and Mg content (Jing et al. 2018). In addition, $V_{cmax}$/LMA was negatively related to LT ($p<0.05$) (Fig. S6c) and LD ($p<0.05$) (Fig. S6d), while $V_{cmax}$ was not correlated to LT and LD (Fig. S6a,b), demonstrating that leaf structure plays an important role in regulating $V_{cmax}$. ” (see page 14 line 405 to page 15 line 412).

(8) Awful sentences, Lines 39-35, should split into short sentences

Response: Rephrased as: “The results showed that $g_s$ and $g_m$ varied about 7.6- and 34.5-fold, respectively, and $g_s$ was positively related to $g_m$. The contribution of $g_m$ to leaf CO$_2$ gradient was similar to that of $g_s$. $g_s/A$, $g_m/A$ and $g_t/A$ was negative related to $V_{cmax}/A$. The relative limitations of $g_s$ ($l_s$), $g_m$ ($l_m$) and $V_{cmax}$ ($l_b$) to A for the whole group (combined 6 life forms) were significantly different from each other ($P<0.05$). $l_m$ was the largest ($0.38 \pm 0.12$), followed by $l_b$ ($0.34 \pm 0.14$) and $l_s$ ($0.28 \pm 0.07$). No significant difference was found between $l_s$, $l_m$, and $l_b$ for Trees and Tree/shrubs, while $l_m$ was the largest, followed by $l_b$ and $l_s$ for Shrubs, Grasses, Viens and Ferns ($P<0.05$). iWUE varied about 3-fold (from 29.52 to 88.92 μmol CO$_2$ mol$^{-1}$ H$_2$O)
across all species, and was significantly correlated with \( g_s \), \( V_{c\text{max}} \), \( g_m/g_s \), and \( V_{c\text{max}}/g_s \).” (see page 3 lines 40-50).

Abstract:
Coexisting plant species in a Karst ecosystem may use diversity strategies of trade off between carbon gain and water loss to adopt to the low soil nutrient and water availability conditions. Understanding of the impact of CO2 diffusion and maximum carboxylase activity of Rubisco ($V_{cmax}$) on the light-saturated net photosynthesis ($A$) and intrinsic water use efficiency (iWUE) can provide insight into physiological strategies of water-carbon regulation of coexisting plant species used in adaptation to Karst environments at the leaf scale. We selected 63 dominant species (across 6 life forms) in a subtropical Karst primary forest in southwestern China, measured their CO2 response curves, and calculated the corresponding stomatal conductance to CO2 ($g_s$), mesophyll conductance to CO2 ($g_m$), and $V_{cmax}$. The results showed that $g_s$ and $g_m$ varied about 7.6- and 34.5-fold, respectively, and $g_s$ was positively related to $g_m$. The contribution of $g_m$ to leaf CO2 gradient was similar to that of $g_s$, $g_s/A$, $g_m/A$ and $g_s/A$ was negative related to $V_{cmax}/A$. The relative limitations of $g_s$ ($l_s$), $g_m$ ($l_m$) and $V_{cmax}$ ($l_b$) to $A$ for the whole group (combined 6 life forms) were significantly different from each other (P<0.05). $l_m$ was the largest (0.38±0.12), followed by $l_b$ (0.34±0.14) and $l_s$ (0.28±0.07). No significant difference was found between $l_s$, $l_m$, and $l_b$ for Trees and Tree/shrubs, while $l_m$ was the largest, followed by $l_b$ and $l_s$ for Shrubs, Grasses, Viens and Ferns (P<0.05). iWUE varied about 3-fold (from 29.52 to 88.92 μmol CO2 mol⁻¹ H₂O) across all species, and was significantly correlated with $g_s$, $V_{cmax}$, $g_m/g_s$, and $V_{cmax}/g_s$. These results indicated that Karst plants maintained relatively high $A$ and low iWUE through the co-variation of $g_s$, $g_m$, and $V_{cmax}$ as adaptation to Karst environment.

Key words: iWUE; mesophyll conductance; stomatal conductance; Karst critical zone; $V_{cmax}$
1 Introduction

Diversity strategies of trade-off between carbon gain and water loss are critical for the survival of coexisting plant species. In order to adapt to the harsh environment, coexisting plant species develop distinct patterns of strategies of carbon-water regulation (light-saturated net photosynthesis (A) and intrinsic water use efficiency (iWUE)) (Sullivan et al., 2017). iWUE is the ratio of A to stomatal conductance to H₂O (gs) (Moreno-Gutierrez et al., 2012). Plants with high iWUE are better able to adapt to the nutrient- and water-limited environment (Flexas et al., 2016). Due to the greater hydraulic erosion and complex underground drainage network (Nie et al., 2014; Chen et al., 2015), Karst soils cannot retain enough nutrients and water for plant growth even though precipitation is high (1000-2000 mm) (Liu et al., 2011; Fu et al., 2012; Chen et al., 2015). Understanding of the impact of CO₂ diffusion and maximum carboxylase activity of Rubisco (V_cmax) on A and iWUE in Karst plants can provide insight into physiological strategies of water-carbon regulation of plants used in adaptation to Karst environments at the leaf scale. Until now, variability in A and iWUE has been reported only in 13 co-occurring trees and 12 vines (Chen et al., 2015), and 12 co-occurring tree species (Fu et al., 2012) in two tropical Karst forests in southwestern China.

Based on Fick's first law, A has been shown to be limited only by leaf stomatal conductance to CO₂ (gs = gsw/1.6) and V_cmax (Flexas et al., 2012; Buckley and Warren, 2014); originally, mesophyll conductance to CO₂ (gm) was proposed to be infinite, i.e. CO₂ concentration in chloroplast (C_c) was equal to the CO₂ concentration in intercellular air space (C_i). However, gm varies greatly among species (Warren and Adams, 2006; Flexas et al., 2013). Recent studies have confirmed that A was constrained jointly by gs, gm, and V_cmax, and their relative contribution to A was species-dependent and site-specific (Carriqui et al., 2015; Tosens et al., 2016; Galmes et al., 2017; Peguero-Pina et al., 2017a; Peguero-Pina et al., 2017b; Veromann-Jurgenson et al., 2017).
Variation in iWUE (=A/gsw) depends on the relative changes in A (gs, gm, Vcmax) and 
gsw (gsw=1.6gs) (Flexas et al., 2013; Gago et al., 2014). Theoretical relationships 
between iWUE and gs, gm, and Vcmax have been deduced using two approaches. Based 
on Fick's first law of CO2 diffusion, Flexas et al. (2013) deduced that iWUE was a 
function of gm/gs and CO2 gradients (Cc-Cc) within a leaf. On the other hand, 
combining Fick's first law of CO2 diffusion and Farquhar biochemical model 
(Farquhar and Sharkey, 1982), Flexas et al. (2016) deduced that iWUE was a function 
of Vcmax/gs, Cc, CO2 compensation point of photosynthesis (I4), and the effective 
Michaelis–Menten constant of Rubisco for CO2 (Km). Until now, most previous 
studies focused on the role of CO2 diffusion in limiting iWUE, and suggested that 
iWUE was negatively related to gs, and positively related to gm/gs (Flexas et al., 2013). 
Gago et al. (2014) used a meta-analysis with 239 species, and were the first to 
confirm that iWUE was positively related to Vcmax/gs. Although both gm/gs and 
Vcmax/gs were positively correlated with iWUE, there was only a weak correlation 
between gm/gs and Vcmax/gs, which indicates that iWUE can be improved by increasing 
Vcmax or gm (proportionally higher than gs), not both (Gago et al., 2014).

It is noteworthy that Flexas et al. (2016) and Gago et al. (2014) found that most of the 
previous work on constraints of gs, gm, and Vcmax on A were conducted in crops or 
saplings, and only a few studies were in natural ecosystems. For example, gm was the 
main factor limiting A in two Antarctic vascular grasses (Saez et al., 2017), and in 35 
Australian sclerophylls (Niinemets et al., 2009b) in different habitats. The A of two 
closely-related Mediterranean Abies species growing in two different habitats was 
mainly constrained by gm in one, and by gs in the other habitat (Peguero-Pina et al., 
2012). Beyond that, it still remains unknown how gsv, gm, and Vcmax regulate A and 
iWUE across species in natural ecosystems.

In this study, we selected 63 dominant plant species, including six life forms (Tree 
(n=29), Tree/Shrub (n=11), Shrub (n=11), Grass (n=11), Vine (n=5), and Fern (n=3)).
from a subtropical primary forest in the Karst critical zone of southwestern China, and measured their $A$ and CO$_2$ response curves. $g_m$ was calculated using the curve-fitting method (Ethier and Livingston, 2004). The obtained $g_m$ was used to transform the $A$-$C_i$ into $A$-$C_c$ response curves, and then to calculate the $A$ and $V_{cmax}$. Our objective was to determine and distinguish the limitations of CO$_2$ diffusion ($g_s$ and $g_m$) and $V_{cmax}$ on $A$ and iWUE in different life forms in this Karst primary forest, and to understand the patterns of strategies of carbon-water regulation of Karst plants.

2 Materials and Methods

2.1 Site information

This study was conducted in a subtropical primary forest (26°14′48″N, 105°45′51″E; elevation, 1460 m), located in the Karst CZ of southwestern China. This region has a typical subtropical monsoon climate, with a mean annual precipitation of 1255 mm, and mean annual air temperature of 15.1°C (Zeng et al., 2016). The soils are characterized by a high ratio of exposed rock, shallow and nonhomogeneous soil cover, and complex underground drainage networks, e.g. grooves, channels and depressions (Chen et al., 2010; Zhang et al., 2011; Wen et al., 2016). Soils and soil water are easily leached into underground drainage networks. Soil texture is silt-clay loam, and soil PH is 6.80±0.16 (Chang et al., 2018). The total nitrogen and phosphorus content in soil is 7.30±0.66 and 1.18±0.35 g Kg$^{-1}$, respectively, which was similar with that of non-Karst CZs (Wang et al., in review). However, the soil quantities (16.04~61.89 Kg m$^{-2}$) and nitrogen and phosphorus storage (12.04 and 1.68 t hm$^{-2}$) is much lower than that of non-Karst CZs, due to the thin and heterogeneous soil layer (He et al., 2008; Jobbagy et al., 2000; Lu et al., 2010; Li et al., 2008). The typical vegetation type is mixed evergreen and broadleaf deciduous primary forest, dominated by *Itea yunnanensis* Franch, *Carpinus pubescens* Burk., and *Lithocarpus confinis* Huang, etc. (Wang et al., 2018).

2.2 Leaf gas-exchange measurements
In July and August 2016, 63 species (Table S1) were selected for measurements of the $A$ and CO$_2$ response curves. The species sampled were selected according to their abundance in the study site. They are the main component of this forest, including 55 woody species (46 deciduous and 10 evergreen species) and 5 herb species. To distinguish the strategies of water-carbon regulation of plants among different life forms, those species were grouped into 6 life forms, including (1) Tree (n=29), (2) Tree/Shrub (n=11), (3) Shrub (n=11), (4) Grass (n=11), (5) Vine (n=5), and (6) Fern (n=3). “Tree/Shrub” is a kind of low wood plant between Tree and Shrub. Fern grow in understory. Vine climb up to the shrub canopy to get light.

Details of leaf sampling and measurements of the CO$_2$ response curve were briefly described as follows. Branches exposed to the sun were excised from the upper part of the crown (Trees, Tree/Shrubs, Shrubs and Vines) or aboveground portion (Grasses, Ferns), and immediately re-cut under water to maintain xylem water continuity. Back into the laboratory, branches and aboveground portions were kept at 25°C for 30 min. Fully-expanded and mature leaves were induced for 30 minutes at a saturating light density (1500 μmol m$^{-2}$ s$^{-1}$). CO$_2$ response curves measurements were performed when $A$ and $g_s$ was stable. Three leaves per species were collected and measured. A total of 189 leaves were collected from adult individuals of 63 species.

The CO$_2$ response curves were measured with 11 CO$_2$ concentration gradients in chamber following the procedural guidelines described by Long and Bernacchi (2003). The photosynthetic photon flux density was 1500 μmol m$^{-2}$ s$^{-1}$. The leaf temperature was 25°C, controlled by the block temperature. The humidity in the leaf chamber was maintained at ambient condition. Leaf area, thickness (LT) and dry mass were measured after the CO$_2$ response measurements. Leaf mass per area (LMA) was calculated by dividing the corresponding dry mass by leaf area. And leaf density (LD) was calculated by dividing the corresponding LMA by LT. More details were described in Wang et al. (2018).
2.3 Response curve analyses

A and the corresponding $g_{sw}$ ($g_{s}=g_{sw}/1.6$), $C_{a}$, and $C_{i}$ were extracted from the CO$_2$ response curve under saturating light (1500 μmol m$^{-2}$ s$^{-1}$) conditions, with CO$_2$ concentration inside the cuvette set to 400 μmol mol$^{-1}$ (Domingues et al., 2010). $V_{cmax}$ was estimated by fitting $A$-$C_{c}$ curves (Ethier and Livingston, 2004). The obtained values of $g_{m}$ were used to transform the $A$-$C_{i}$ into $A$-$C_{c}$ response curves as $C_{c}=C_{i}-A/g_{m}$.

Three methods are most commonly used for $g_{m}$ estimation. Those methods have been reviewed by Warren (2006) and Pons et al. (2009). Briefly, $g_{m}$ can be calculated by the stable isotope method (Evans, 1983; Sharkey et al., 1991; Loreto et al., 1992), $J$ method (Bongi and Loreto, 1989; Dimarco et al., 1990; Harley et al., 1992; Epron et al., 1995; Laisk et al., 2005), and ‘curve-fitting’ method (Ethier and Livingston, 2004; Sharkey et al., 2007). All of these methods are based on gas exchange measurements (Pons et al., 2009), and some common assumptions (Warren, 2006). Thus, the accuracy of each method is to some extent unknown (Warren, 2006).

$g_{m}$ was estimated by the ‘curve-fitting’ method in this study. Although the ‘curve-fitting’ method is less precise than the stable isotope method, the ‘curve-fitting’ method is much more readily available and has been used for several decades (Warren, 2006; Sharkey, 2012). Accurate measurements of $A$ and $C_{i}$ is a prerequisite for estimating $g_{m}$ using the ‘curve-fitting’ method (Pons et al., 2009). Warren (2006) pointed out that highly-accurate measurements need small leaf area and low flow rates. We confirmed that the calculated $C_{c}$ and the initial slope of $A$-$C_{c}$ curves were positive, suggesting that the measured $g_{m}$ was reliable (Warren, 2006).

2.4 Theory of trade-off between carbon and water at leaf scale

The exchange of H$_2$O and CO$_2$ between the leaf and the atmosphere is regulated by stomata (Gago et al., 2014). According to Fick’s first law of diffusion, $A$ and $g_{s}$ are
related as:

\[ A = g_s (C_a - C_i) \]  

(1)

where \( A \) is the photosynthetic rate (\( \mu \text{mol} \text{ CO}_2 \text{ m}^{-2} \text{ s}^{-1} \)); \( C_a \) is the ambient CO\(_2\) concentration (\( \mu \text{mol} \text{ mol}^{-1} \)); \( C_i \) is the intercellular CO\(_2\) concentration (\( \mu \text{mol} \text{ mol}^{-1} \)).

**Mesophyll is the** barrier for CO\(_2\) inside the leaf. \( A \) and mesophyll conductance to CO\(_2\) are related as:

\[ A = g_m (C_i - C_c) \]  

(2)

where \( C_c \) is the CO\(_2\) concentration at the sites of carboxylation (\( \mu \text{mol} \text{ mol}^{-1} \)). \( C_c \) not only depends on CO\(_2\) supply by \( g_m \), but also on CO\(_2\) demand (the maximum carboxylase activity of Rubisco, \( V_{\text{cmax}} \)).

(1) **The relationship between iWUE and** \( g_m/g_s \)

iWUE is a function of CO\(_2\) diffusion conductances (e.g. \( g_s \) and \( g_m \)) and leaf CO\(_2\) concentration gradients. We can express \( A \) as the product of the total CO\(_2\) diffusion conductance \( g_t \) from ambient air to chloroplasts, and the corresponding CO\(_2\) concentration gradients by combining Eq. (1) and (2) (Flexas et al., 2013):

\[ A = g_t [(C_a - C_i) + (C_i - C_c)] \]  

(3)

where \( g_t = 1/(1/g_s + 1/g_m) \). This equation demonstrates that CO\(_2\) concentration gradients in leaves are constrained by stomatal and mesophyll resistance to CO\(_2\). Therefore, iWUE can be expressed as:

\[ \frac{A}{g_{sw}} = \frac{1}{1.6} \left( \frac{g_m/g_s}{1+g_m/g_s} \right) [(C_a - C_i) + (C_i - C_c)] \]  

(4)

Eq. (4) means that iWUE is positively related to \( g_m/g_s \), but not to \( g_m \) itself (Warren and Adams, 2006; Flexas et al., 2013; Buckley and Warren, 2014; Cano et al., 2014).

(2) **The relationship between** iWUE and \( V_{\text{cmax}}/g_s \)

When Fick’s first law and the Farquhar biochemical model (Farquhar and Sharkey, 1982) are combined, iWUE is also a function of \( V_{\text{cmax}} \). Based on the Farquhar biochemical model (Farquhar and Sharkey, 1982), when \( A \) is limited by Rubisco, it
can be expressed by the following equation (Sharkey et al., 2007):

\[ A = \frac{V_{\text{max}}(C_e - \Gamma^*) - R_d}{(C_e + K_m)} \]  

(5)

where \( \Gamma^* \) is the CO\(_2\) compensation point of photosynthesis in the absence of non-photorespiratory respiration in light (\( R_d \)), and \( K_m \) is the effective Michaelis–Menten constant of Rubisco for CO\(_2\). Combining Eq. (1) and (5) (Flexas et al., 2016), we obtain:

\[ \frac{V_{\text{max}}}{g_s} = \frac{(C_e + K_m)(C_e - C_i)(A + R_d)}{(C_e - \Gamma^*)A} \]  

(6)

Because \( R_d \) is much smaller than \( A \) in actively photosynthesizing leaves, \( \frac{V_{\text{max}}}{g_s} \) can be approximated as:

\[ \frac{V_{\text{max}}}{g_s} \approx \frac{(C_e + K_m)(C_e - C_i)}{(C_e - \Gamma^*)} \frac{A}{g_s} \]  

(7)

Consequently, \( i\text{WUE} \) can be expressed as:

\[ \frac{A}{g_{sw}} = \frac{1}{1.6} \frac{V_{\text{max}}}{g_s} \frac{(C_e - \Gamma^*)}{(C_e + K_m)} \]  

(8)

### 2.5 Statistical analysis

(1) Quantitative analysis of limitations on \( A \)

The relative contribution of \( g_s \) \( (l_s) \), \( g_m \) \( (l_m) \) and \( V_{\text{max}} \) \( (l_b) \) to \( A \) can be separated by a quantitative limitation model introduced by Jones (Jones, 1985) and further developed by Grassi & Magnani (2005). The sum of \( l_s \), \( l_m \), and \( l_b \) is 1. \( l_s \), \( l_m \) and \( l_b \) can be calculated as:

\[ l_s = \frac{g_s / g_s \cdot \partial A / \partial C_e}{g_s / \partial A / \partial C_e} \]  

(9)

\[ l_m = \frac{g_m / g_m \cdot \partial A / \partial C_e}{g_m / \partial A / \partial C_e} \]  

(10)

\[ l_b = \frac{g_b}{g_b / \partial A / \partial C_e} \]  

(11)
where $\partial A / \partial C_c$ was calculated as the slope of $A-C_c$ response curves over a $C_c$ range of 50–100 μmol mol$^{-1}$. $l_s$, $l_m$ and $l_b$ have no units. $A$ is co-limited by the three factors when $l_s \approx 0.3$, $l_m \approx 0.3$ and $l_b \approx 0.4$ (Galmes, J. et al., 2017).

(2) Data analysis

Data were analyzed either as a whole group (six life forms combined) or by individual life forms. The bivariate linear regressions of leaf gas exchange parameters were performed using the standardized major axis (SMA) regression fits, and all of the data were made on log$_e$-transformed data (Table S2).

To test for the differences among life forms, SMA regression fits were used to compare the slope of regression lines which significant relationships had already been obtained. Note that Grass, Vine and Fern were not considered due to the small sample size. A similar trend was obtained, and no significant difference was found between life forms although significant relationships were not obtained for some bivariate linear regressions. Accordingly, six life forms were grouped together to analyze the strategy of water-carbon regulation of plants in the whole text.

The difference of relative limitation of $g_s$, $g_m$ and $V_{cmax}$ to $A$ for life forms or as a whole group were performed using one-way ANOVA and Duncan multiple comparison. The probability of significance was defined at $p < 0.05$.

3 Results

3.1 Interrelation among $g_s$, $g_m$, $g_t$, and $V_{cmax}$

CO$_2$ concentration gradients in leaf were controlled by CO$_2$ diffusion conductance and $V_{cmax}$. Fig. 1 shows the relationship between CO$_2$ gradients ($C_a-C_i$, $C_i-C_c$ and $C_a-C_c$) in leaf and the corresponding CO$_2$ diffusion conductance ($g_s$, $g_m$ and $g_t$) (Fig. 1a-c), and between $C_a-C_c$ and $V_{cmax}$ (Fig. 1d). CO$_2$ concentration gradients ($C_a-C_i$,

\[ C_1-C_c \text{ and } C_a-C_c \] were significantly negatively associated with the corresponding CO₂ diffusion conductance \((g_s, g_m \text{ and } g_t)\) \((P<0.001)\). \(V_{\text{cmax}}\) was positively associated with \(C_a-C_c\) \((P<0.001)\).

\(g_s, g_m, \text{ and } g_t\) were significantly positively related to each other \((P<0.001)\) (Fig. S1).

The contribution of \(g_m\) to leaf CO₂ gradient was similar to that of \(g_s\). The contribution of \(g_s\) \((57.51–155.13 \text{ µmol mol}^{-1})\) to \(C_a-C_c\) \((98.50–282.94 \text{ µmol mol}^{-1})\) varied from 28% to 86%, and the contribution of \(g_m\) \((18.15–179.36 \text{ µmol mol}^{-1})\) to \(C_a-C_c\) varied from 14% to 72%. But the variation range of \(g_m\) \((0.02 –0.69 \text{ mol CO}_2 \text{ m}^{-2} \text{ s}^{-1})\) was 4.5 times that of \(g_s\) \((0.05–0.38 \text{ mol CO}_2 \text{ m}^{-2} \text{ s}^{-1})\).

No relationship was found between the CO₂ diffusion conductance \((g_s, g_m, \text{ and } g_t)\) and \(V_{\text{cmax}}\) (Fig. S2). However, after normalization of \(g_s, g_m, g_t, \text{ and } V_{\text{cmax}}\) for \(A_0\) (normalized parameters are hereafter called \(G_S=g_S/A, G_m=g_m/A, G_I=g_I/A, \text{ and } V=V_{\text{cmax}}/A\)), \(V\) was significantly positively correlated with \(G_m\) and \(G_I\) \((P<0.001)\) (Fig. 2b and c), and was slightly positively correlated with \(G_s\) \((P<0.05)\) (Fig. 2a), which represented the trade-off between CO₂ supply and demand.

### 3.2 Contribution of \(g_s, g_m\) and \(V_{\text{cmax}}\) to \(A\)

The variation in \(A\) was attributed to variation in \(g_s, g_m, g_t, \text{ and } V_{\text{cmax}}\). \(A\) was positively correlated with \(g_s\) (Fig. 3a), \(g_m\) (Fig. 3b), and \(V_{\text{cmax}}\) (Fig. 3c). We used the quantitative limitation model (Eqs. (9), (10) and (11)) to separate \(g_s\) \((l_s)\), \(g_m\) \((l_m)\), and \(V_{\text{cmax}}\) \((l_b)\) limitations to \(A\). \(l_s, l_m, \text{ and } l_b\) were negatively associated with \(g_s, g_m, \text{ and } V_{\text{cmax}}\), respectively (Fig. 4). The contributions by \(g_s, g_m, \text{ and } V_{\text{cmax}}\) to limiting \(A\) were different for each species (Fig. S3). \(l_s\) varied 2.6-fold \((0.17 \text{ to } 0.45)\), \(l_m\) varied 10.5-fold \((0.05 \text{ to } 0.55)\), and \(l_b\) varied 6.2-fold \((0.11 \text{ to } 0.68)\) across species. Overall, \(l_m\) \((0.38±0.12)\) was significantly larger than \(l_b\) \((0.34±0.14)\), and \(l_s\) \((0.28±0.07)\) \((P<0.05)\).
To further understand how $A$ was limited by $g_s$, $g_m$, and $V_{cmax}$ among life forms, we grouped the 63 species into 6 life forms: Tree, Tree/Shrub, Shrub, Grass, Vine, and Fern. The results showed that there was no significantly difference between $l_s$, $l_m$ and $l_b$ for Trees and Tree/shrubs. $l_m$ of Shrubs and Grasses was significantly higher than that of $l_s$ and $l_b$ ($P<0.05$). $l_m$ of Vines and Ferns was significantly higher than that of $l_s$ ($P<0.05$) (Fig. 5).

### 3.3 Effect of $g_s$, $g_m$ and $V_{cmax}$ on iWUE

iWUE varied from 29.52 to 88.92 μmol CO$_2$ mol$^{-1}$ H$_2$O. In theory, iWUE is regulated by $g_s$ ($g_{sw}=1.6g_s$), $g_m$, and $V_{cmax}$. However, a simple correlation analysis showed that iWUE was negatively related to $g_s$ (Fig. 6b), and not related to $A$ (Fig. 6a), $g_m$ (Fig. 6c), and $V_{cmax}$ (Fig. 6d).

A correlation analysis was used to test how $g_m/g_s$ and $V_{cmax}/g_s$ affected iWUE. The results showed that iWUE was positively correlated with $g_m/g_s$ (Fig. 7a) and $V_{cmax}/g_s$ (Fig. 7b). However, there was no significant relationship between $g_m/g_s$ and $V_{cmax}/g_s$.

iWUE was regulated by co-variation between $g_s$, $g_m$ and $V_{cmax}$.

### 4 Discussion

#### 4.1 Co-variation in $g_s$, $g_m$ and $V_{cmax}$ in regulating $A$

$A$ was constrained by $g_s$, $g_m$, and $V_{cmax}$ acting together, however, variability in the relative contribution of these three factors depended on species and habitats (Tosens et al., 2016; Galmes et al., 2017; Peguero-Pina et al., 2017a; Veromann-Jurgenson et al., 2017). $A$ was significantly correlated with $g_s$, $g_m$, and $V_{cmax}$ (Fig. 3a-c). $g_s$ was positively related to $g_m$ (Fig. S1c), while no relationship was found between the CO$_2$ diffusion conductance ($g_s$ and $g_m$) and $V_{cmax}$ (Fig. S2). The relative limitations of $g_s$, $g_m$, and $V_{cmax}$ were separated by a quantitative limitation model (Jones, 1985; Grassi & Magnani, 2005). The results showed that $l_s$, $l_m$ and $l_b$ of 63 species varied in a large range (Fig. S3), indicating plants have a diverse strategies to co-ordinate the CO$_2$
diffusion ($g_s$ and $g_m$) and $V_{cmax}$ to maintain relative high $A$. The order of factors limitations to $A$ was $l_m > l_b > l_s$ (P<0.05) (Fig.S3). Furthermore, we tested the relationship between the relative limitations and the corresponding limitation factors. The results showed that $l_s$, $l_m$, and $l_b$ were negatively associated with $g_s$, $g_m$, and $V_{cmax}$, respectively (Fig. 4). And the relationship was stronger for $g_m$- $l_m$ ($r^2=0.65$) than $V_{cmax}$- $l_b$ ($r^2=0.27$) and $g_s$- $l_s$ ($r^2=0.19$).

$g_s$ was better correlated with $A$, while the results showed that $A$ was more limited by $g_m$. That could be explained by two possible reasons. Firstly, compare to the linear relationship between $A$ and $g_s$, a nonlinear trend has been found between $A$ and $g_m$ when $g_m>0.4$ (Fig. 3a, b). Secondly, leaf structure plays an important role in regulating $g_m$ and $V_{cmax}$, consequently, in determining $A$ (Veromann-Jurgenson et al., 2017). Negative relationships between $A$/LMA and LT ($r^2=0.16$, p=0.002), and $A$/LMA and LT ($r^2=0.3$, p<0.001) have been observed (Fig. S4c,d), while $A$ was not correlated to LT and LD (Fig. S4a,b).

The importance of $g_m$ in constraining $A$ was variable, and depended on leaf structural traits, only LMA, LT, and LD were analyzed in this study. Large variability in $g_m$ has been shown both between and within species with different life forms and habits (Gago et al., 2014; Flexas et al., 2016). Variability in $g_m$ in this study is similar to that in global datasets (Gago et al., 2014; Flexas et al., 2016). There was no significantly difference among life forms (P>0.05). Previous studies have confirmed that LMA (Tomas et al., 2013), thickness of leaf cell wall (Peguero-Pina et al., 2017b), liquid phase of mesophyll (Veromann-Jurgenson et al., 2017), cell wall thickness of mesophyll (Terashima et al., 2011;Tosens et al., 2016), and surface area of mesophyll and chloroplast exposed to intercellular space (Veromann-Jurgenson et al., 2017) were the main limitations for $g_m$. The wide variability of $g_m$ between different species and life forms in the same ecosystem seems to be related to the diversity of leaf anatomical traits.
No significant difference of LMA, LT, and LD was found among life forms (P<0.05).

The negative correlation of $g_m$ (Terashima et al., 2005) or $g_m$/LMA (Ninemets et al., 2009; Veromann-Jurgenson et al., 2017) with LMA have been reported. In this study, there was a significant relationship between $g_m$/LMA with LMA (P<0.01), however, no relationship was found between $g_m$ with LMA. $g_m$/LMA was significantly negative related to LD (p<0.01) (Fig. S5c), and weak negative related to LT (p=0.06) (Fig. S5d), demonstrating that the negative role of cell wall thickness on $g_m$ (Terashima et al., 2006; Ninemets et al., 2009). The strong investment in supportive structures was the main reason for the limitation of $g_m$ on $A$ (Veromann-Jurgenson et al., 2017).

However, it is still unknown how leaf anatomical traits affect $g_m$ and $A$, and this should be further explored.

g_s is responsible for CO$_2$ exchange between atmosphere and leaf, and regulate the CO$_2$ fixation ($A$) and water loss (Lawson and Blatt, 2014). The variability of $g_s$ was controlled by stomatal anatomy, i.e. stomata density and size, and mesophyll demands for CO$_2$ (Lawson and Blatt, 2014). However, the stomatal anatomy was not analyzed in this study. We only focused on how the relationship between $g_s$ and $g_m$ regulate $A$.

Positive relationship between $g_s$ and $g_m$ has been observed (Flexas et al., 2013). For example, the restricted CO$_2$ diffusion from the ambient air to chloroplast is the main reason for a decreased $A$ under water stress conditions due to both the stomatal and mesophyll limitations (Olsovska et al., 2016). $g_s$ was significantly positive related to $g_m$ for 63 species (P<0.001, Fig. S1) in this study, and no difference of the slopes of regression lines between $g_s$ and $g_m$ was found among life forms, demonstrating that $A$ was regulated by the co-variation of $g_s$ and $g_m$. However, the variability of $g_m$ and $l_m$ was larger than $g_s$ and $l_s$, respectively (Fig.1 and Fig.S3).

The wide variation range of $l_b$ (0.11-0.68) highlighted the importance role of $V_{cmax}$ in regulating $A$. $V_{cmax}$ was used to represent the CO$_2$ demand in photosynthetic process in this study. The relative contribution of $V_{cmax}$ to $A$ not only depends on $C_a$-$C_c$, but also on leaf nutrient levels. Positive relationship was found between $C_a$-$C_c$ and $V_{cmax}$ (Fig.
1d). And the $V_{cmax}$/LMA was co-regulated by leaf N, P and Mg content (Jing et al. 2018). In addition, $V_{cmax}$/LMA was negatively related to LT ($p<0.05$) (Fig. S6c) and LD ($p<0.05$) (Fig. S6d), while $V_{cmax}$ was not correlated to LT and LD (Fig. S6a,b), demonstrating that leaf structure plays an important role in regulating $V_{cmax}$.

The trade-off between CO$_2$ supply ($g_s$ and $g_m$) and demand (carboxylation capacity of Rubisco) can help maintain relative high $A$ (Galmes et al., 2017; Saez et al., 2017). In this study, we used $V_{cmax}$ as a proxy for the carboxylation capacity of Rubisco, and the normalized $V_{cmax}$ by $A$ ($V=V_{cmax}/A$) was significantly negatively correlated with the normalized $g_t$ by $A$ ($G_t=g_t/A$) ($p<0.001$) (Fig. 2c), indicating that the trade-off between CO$_2$ supply and demand also existed among different species in the same ecosystems. For genus Limonium (flowering plants) (Galmes et al., 2017), $g_t$ was significantly positively related to Rubisco carboxylase specific activity, and significantly negatively related to Rubisco specificity factor to CO$_2$. In case of Antarctic vascular (Saez et al., 2017) and Mediterranean plants (Flexas et al., 2014), $A$ was mainly limited by low $g_m$, but it could be partially counterbalanced by a highly efficient Rubisco through high specificity for CO$_2$. This highlights the importance of the trade-off between CO$_2$ supply and demand in plant adaptation to Karst environment. However, it is still unknown how leaf anatomical traits affect $g_m$, $V_{cmax}$ and $A$, and this should be further explored.

### 4.2 Co-variation of $g_s$, $g_m$ and $V_{cmax}$ in regulating iWUE

Compared with the global dataset under well-watered conditions (19.27-171.88 μmol CO$_2$ mol$^{-1}$ H$_2$O) (Flexas et al., 2016), iWUE (52.85±13.08 μmol CO$_2$ mol$^{-1}$ H$_2$O) was somewhat lower in this study. iWUE varied from 29.53 to 88.91 μmol CO$_2$ mol$^{-1}$ H$_2$O, and the variability of iWUE was larger than in the Karst tropical primary forest (Fu et al., 2012; Chen et al., 2015). The average iWUE of 12 Vines and 13 Trees in the Karst tropical primary forest was 41.23±13.21 μmol CO$_2$ mol$^{-1}$ H$_2$O (Chen et al., 2015), while that of 6 evergreen and 6 deciduous Trees was 66.7±4.9 and 49.7±2.0
\[ \mu \text{mol CO}_2/\text{mol H}_2\text{O}, \text{ respectively} \] (Fu et al., 2012). The results demonstrated that Karst plants use a diverse strategies of carbon-water regulation to adopt to the harsh Karst environment.

Coexisting species have a diversity strategies of carbon-water regulation, ranging from ‘profligate/opportunistic’ to ‘conservative’, that means their ecophysiological niche are separate (Moreno-Gutierrez et al., 2012; Nie et al., 2014; Prentice et al., 2014). Species with high \( g_s \), and low iWUE were defined to have ‘profligate/opportunistic’ water use strategy, and species with low \( g_s \) and high iWUE were defined to exhibit ‘conservative’ water use strategy (Moreno-Gutierrez et al., 2012). In consistent with previous study (Moreno-Gutierrez et al., 2012), coexisting plant species growing in the Karst ecosystem had a diversity water use strategies. However, Karst plants tended to lose more water to gain more carbon, i.e. Karst plants used ‘profligate/opportunistic’ water use strategy to adopt to the low nutrient availability and water stress conditions.

Prentice et al. (2014) studied the trade-off between carbon gain and water loss of woody species in contrasting climates, and found that species in hot and wet regions tend to lose more water in order to fix more carbon (high \( g_s/A \), low \( V_{\text{cmax,Cl}/A} \)), and vice versa. Although Karst soils cannot contain enough water for plant growth, the trade-off between carbon gain and water loss (high \( g_s/A \) and low \( V_{\text{cmax,Cl}/A} \)) were similar to the shown for plants growing in hot and wet regions (Prentice et al., 2014).

iWUE is regulated by the co-variation of \( g_s, g_m \), and \( V_{\text{cmax}} \). In theory, water loss is regulated by \( g_s \) only, while carbon gain (\( A \)) was regulated by \( g_s, g_m \), and \( V_{\text{cmax}} \) (Lawson and and Blatt, 2014). However, iWUE in this study was negatively related to \( g_s \) (\( R^2=0.30 \)), negatively related to \( V_{\text{cmax}} \) (\( R^2=0.09 \)), and not related to \( A, g_m \) (Fig. 6).

CO\(_2\) diffusion and Farquhar biochemical model indicated that iWUE is affected by \( g_m/g_s \) and \( V_{\text{cmax}}/g_s \) (Gago et al., 2014; Flexas et al., 2016). There was a hyperbolic
dependency of iWUE on $g_m/g_s$ due to the roles of $g_s$ and $g_m$ in $C_i$ and $C_c$, and of $C_c$ in $A$ (Flexas et al., 2016). In meta-analyses, both Gago et al. (2014) and Flexas et al. (2016) found that iWUE was significantly positively related to $g_m/g_s$ and $V_{cmax}/g_s$. The results of this study are consistent with the meta-analyses (Fig. 7), demonstrating that plant species with relatively high $g_m/g_s$ or $V_{cmax}/g_s$ had relatively high iWUE. The relationship between iWUE and $V_{cmax}/g_s$ ($R^2=0.50$) was stronger than the relationship between iWUE and $g_m/g_s$ ($R^2=0.20$), demonstrating iWUE was mainly regulated by $V_{cmax}/g_s$. The reason maybe that iWUE was correlated to $g_s$ and $V_{cmax}$, and $g_s$ was positive related to $g_m$.

However, plants cannot simultaneously have high $g_m/g_s$ and high $V_{cmax}/g_s$. Similarly to the study of Gago et al. (2014), we found no relationship between $g_m/g_s$ and $V_{cmax}/g_s$. Gago et al. (2014) thought that the poor relationship between $g_m/g_s$ and $V_{cmax}/g_s$ indicated that the iWUE may be improved by $g_m/g_s$ or $V_{cmax}/g_s$ separately; if both of them were simultaneously improved, the enhanced effect on iWUE could be anticipated. In addition, Flexas et al. (2016) showed in a simulation that the increase in iWUE caused by overinvestment in photosynthetic capacity would progressively lead to inefficiency in the trade-off between carbon gain and water use, causing an imbalance between CO$_2$ supply and demand.

5 Conclusions

This study provides information of limitations of $A$ and iWUE by $g_s$, $g_m$, and $V_{cmax}$ in 63 species across 6 life forms in the field. The results showed that plants growing in Karst CZs used a diverse strategies of carbon-water regulation, but no difference was found among life forms. The co-variation of CO$_2$ supply ($g_s$ and $g_m$) and demand ($V_{cmax}$) regulated $A$, indicating that species maintain a relatively high $A$ through co-varing their leaf anatomical structure and $V_{cmax}$. iWUE was relatively low, but ranged widely, indicating that plants used the ‘profligate/opportunistic’ water use strategy to maintain the survival, growth, and structure of the community. iWUE was
regulated by $g_s$, $V_{cmax}$, $g_m/g_s$ and $V_{cmax}/g_s$, indicating that species with high $g_m/g_s$ or $V_{cmax}/g_s$ will have to be much more competitive to response to the ongoing rapid warming and drought in the Karst CZs.
